Recommended vaccines

Rotavirus

Protects against rotavirus, an extremely common stomach virus that causes severe diarrhoea, vomiting and fever. Rotavirus infection is most frequent and severe in infants between 3-24 months old and severe infections can cause dehydration, in which case, hospitalisation is needed to avoid complications.

The rotavirus vaccine comes as an ORAL 2-dose regimen. Can be taken on the same clinic visit as your baby's Infanrix vaccination. Course must be completed by 6 months of age.

Varicella (also known as chickenpox)

Protects against chickenpox, a highly contagious childhood disease.

Characterised by fever and small, red, itchy blisters on the body and face. Complications include scarring, shingles and central nervous system manifestations.

The vaccine formulation comes either as a Varilrix injection or as a component of the "4in1" MMRV vaccine, called Priorix-Tetra protecting against Measles, Mumps, Rubella and Varicella.

Two doses of MMRV, a new baby-friendly vaccine, is recommended for optimal protection without the hassle of extra injections.

Pneumococcal

Protects against pneumococcal infections caused by a germ called *Streptococcus pneumoniae*. This germ can cause mild illnesses, such as sinus and ear infections, or life-threatening infections such as pneumonia, meningitis, and infections of the bloodstream.
